

ABSTRACT

[0080] Candleholders suitable for outdoor use include a base unit for holding a candle, this unit having a candle supporting surface and an upstanding wall portion, and a separate cover member for placement over the candle or candles and the base unit. The cover member forms a top and a peripheral wall section. The candleholder has a plurality of openings located between the supporting surface and the top. The preferred openings are formed by partially cutting out and bending small sections of one of the upstanding wall portion and the wall section inward so as to permit entry of combustion air while also normally changing the direction of airflow of the incoming air. In one version, there is also a main housing adapted for mounting below ground level, this housing having an open top and a peripheral side wall portion that extends upwardly from a concrete bottom.
